

Covalent Lewis Dot Structures

Covalent Lewis Dot Structures: formulas used to model what atoms look like in a compound that contains atoms that are covalently bonded together.

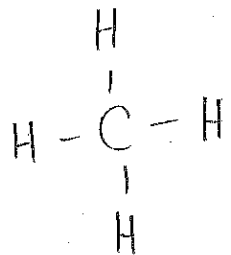

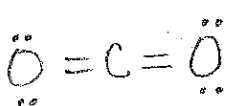

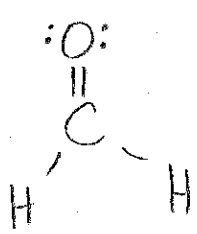

- Non-metals will share electrons to get 8 valence electrons and be stable.

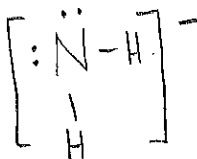

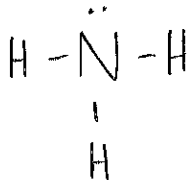

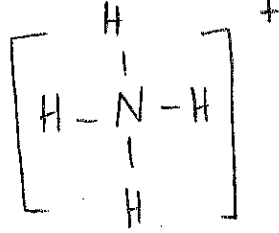

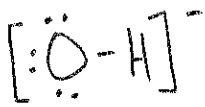

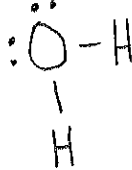

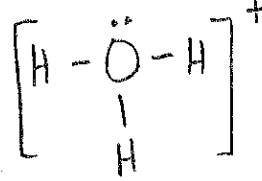

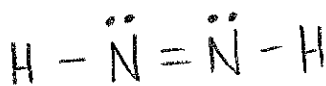

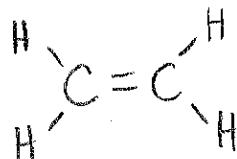

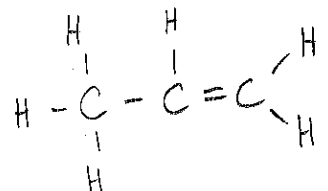

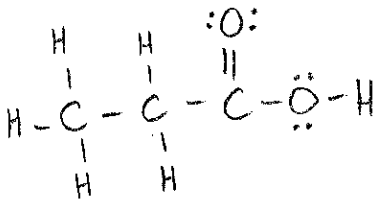

Helpful Hints for Drawing Lewis Dot Structures

- H is always a terminal atom → ALWAYS connected to only 1 other atom.
- Lowest electronegativity is central atom in molecule.
- If drawing the Lewis structure for a polyatomic ion,
 - For positive ions, subtract electron(s) from the central atom.
 - For negative ions, add electron(s) to the central atom.
 - Enclose the dot structure in square brackets and include the ion's charge outside the brackets.
- Not all elements can form double or triple bonds: **only C, N, O, P, and S!** (Think CNOP-S)
- For molecules with more than one central atom, use the formula to help you decide how to draw the structure.
- The total number of valence electrons in your Lewis structure MUST equal the # of the valence electrons of all of the elements (add or subtract electrons as needed for polyatomic ions).
- For *most* covalent compounds, you can determine how many bonds each atom will form by looking at the number of unpaired electrons in their Lewis dot structure.
 - Paired electrons do NOT form bonds.
 - Single electrons do form bonds!

H H. # bonds? <u>1</u>	Be Be. # bonds? <u>2</u>	B B. # bonds? <u>3</u>	C C. # bonds? <u>4</u>	N N. # bonds? <u>3</u>	O O. # bonds? <u>2</u>	F F. # bonds? <u>1</u>
-------------------------------------	---------------------------------------	-------------------------------------	-------------------------------------	-------------------------------------	-------------------------------------	-------------------------------------

Examples:

CH ₄ 	CO ₂ 	CH ₂ O 
--	--	--

NH_2^- 	NH_3 	NH_4^+ 
OH^- 	H_2O 	H_3O^+ 
N_2H_2 	CH_2CH_2 	
CH_3CHCH_2 	$\text{CH}_3\text{CH}_2\text{COOH}$ 	

But wait!!! Exceptions to the octet rule

1. Elements that will have less than 8 valence electrons and are stable.

- Hydrogen, 2 electrons (1 bond)
- Beryllium, 4 electrons (2 bonds)
- Boron, 6 electrons (3 bond)

2. Elements that will have more than 8 valence electrons and are stable.

- Elements in period (row) 3 through 7 can often expand their octet and can form more than 4 bonds (can have up to 12 electrons, 6 bonds)
 - This is only possible between periods 3 through 7 because they can hold electrons in their empty d sublevel.
 - If you are unsure where to put extra lone pairs, check to see if the central atom can have an expanded octet (check to see if the element is in periods 3 through 7)

Challenge: Lewis Dot Practice, including exceptions to the octet rule. ☺

RnCl₂

$$8 - 2 = \boxed{6}$$
